KEY PERFORMANCE INDICATORS IN A HIGH EDUCATIONAL INSTITUTION: A BUSINESS INTELLIGENCE APPROACH

Master in Technology and Management of Information Systems

Supervisor
Pedro Castro
Co-supervisor
Miguel Bento Alves

October 2010
Program was supported by ERASMUS MUNDUS External Cooperation Window for Georgia, Armenia and Azerbaijan (Lot 5)
I dedicate this project to my parents, to my relatives, to my friends.
Acknowledgement

I would like to say that I appreciate the help from Polytechnic Institute Viana do Castelo. Direct thanks to my supervisors Professor Pedro Castro and co-supervisor Mr. Professor Miguel Bento Alves for their support during the thesis preparation.

I want express my gratitude to Professor Jorge Ribeiro, who helped me a lot during my work. He provided me with books, materials and his advice was always extremely helpful.

I want to say many thanks to my teachers in IPVC Institute, to Professor Sara Paiva, Professor Antonio Miguel Cruz, Professor Rui Gomes and others. And special thank to Elsa Coelho and Sónia Simas, I would like to express my thanks to them for cooperation and support during my studies in Portugal. I am very thankful that they gave me the thorough knowledge and inspired me to work in this field.

My special thanks go to the European Commission, Education, Audiovisual and Culture Executive Agency (EACEA) and to my Erasmus Mundus program coordinator in Greece - Prof. Tania Kapiki. She gave me the opportunity to do my Master’s degree in Portugal. It was a great challenge and a wonderful experience to be an Erasmus Mundus student. It was a great chance to meet other international students and I have lots of good memories that are never going to fade.

Special thanks to Professor Marina Javakhishvili in Georgia – Telavi State University coordinator of International Exchange office for her support and assistant during my participation in this program.

I want to say great thanks to Boris Elvison, Vice President and Principal Analyst at Forrester Research. I was very happy when I received his reply providing me with the up-to-date materials related to my research work.

Many thanks to Paruyr Khnkoyan (Employee in Synopsys http://www.synopsys.com as a Software Engineer II, December 2006 - April 2010, Yerevan-Armenia); I received his assistance and consultations during my thesis document preparation.
Abstract

Nowadays it is impossible for organizations to perform business activities without using the Information and Communication Technologies (ICT), which includes computers, networks hardware and applications. Usually organizations use applications to perform their business processes storing daily transactional data related to products, customers and other entities into operational databases. Operational databases are embedded into applications in order to provide to users mechanisms to analyze data and get reports from different points of view. On the other hand, there is an increasing amount of data stored in operational databases, which can be used in analytical reports in order to help managers in decision making activities. In this context, it is important for organizations to evaluate if their applications work well and answer to the business requirements, as well as control all business processes in all organization’s levels, namely, produce reliable and high quality products, increase customers’ satisfaction, improve application performances and the quality of services provided to costumers and collaborators. For this purpose, organizations have the opportunity to comply with ISO (International Organization of Standards) requirements, guidelines and instructions in order to improve quality of processes, and then achieve the Quality Management System (QMS) in different levels of the organization.

In order to improve business performances in enterprises, decision makers define key performance indicators (KPI) for all (or some) business processes, which are based according to their strategies and goals, to evaluate, control and monitor services in order to improve business activities. For this purpose, Business Intelligence (BI) system demonstrates to be a possible solution to achieve this issue, allowing to integrate all enterprise operational data into a single data repository, get analytical data and generate reports. In general, a BI application is a meta-data driving tool, which has the capability to extract data from different systems and store them into a data repository (also called a data warehouse). It gives the opportunity to gather, store, filter and analyze huge volumes of data, providing to access historical data and develop set of reports in a quick and easy manner in order to support decision making activities.

During the last years there are many examples of the application of BI systems in different types of organizations. BI systems can also be used in educational institutions. Applying BI in educational institutions gives the opportunity to integrate all
data of educational processes into data warehouses, from where it is possible to deliver KPI reports for decision makers through the use of Online Analytical Processing tools. In this context, this project focuses to apply BI systems in a Quality Management System (ISO 9001 Standard) implemented in a high educational institution (Polytechnic Institute of Viana do Castelo), with the objective to provide analytical tools to decision makers in order to evaluate, control, monitor and improve educational performances in all levels of the institution. With this work we have developed a BI application to provide IPVC decision makers with management tools to analyze data from QMS and get KPI reports with the purpose to satisfy the needs and expectations of IPVC managers.

Chapter 1 – Introduction

1.1 Background

Nowadays, we live in an information age where huge volumes of information are stored around us and we have to choose from mountains of data to produce useful information. Very often we have difficulties to find and choose the right information, losing resources and a lot of time filtering and sorting data in order to find the right one from the huge of data volumes which are collected and produced by organizations. People waste a tremendous amount of time trying to find and sort through the information in order to perform their tasks. According to Forrester Consulting research [1 p. 23], “office workers spend 42% on working on information and 58% using the information making reports and analyzing”.

Indeed, the data produced and stored by enterprises increases overtime as a result of their internal and external processes, which are related to their products and customers services. In this context, organizations have the objective to reduce the amount of time consumed on searching and sorting through mountains of data and spend more time on analysis and making decisions.

In a competitive environment, organizations need to have the right and on time information in order to be able to get advanced position in the markets. Traditionally, in enterprises, information is located in various internal or external places in different sources and for business people (for example the managers and decision makers), it becomes harder and harder to find the right information, which consumes a lot of time and energy. In this context, Business Intelligence (BI) Systems are used to overcome these difficulties, since they enable to get quickly needed information by transforming mountain of data into meaningful, useful and insightful information, which will help to meet business requirements to make real time decisions. In recent years, demands for BI systems are increasing in enterprises. BI systems begin to rise due to the increasing data volumes, the growing of complex business operations, the necessity to generate reports with increasing complexity and the need to answer to complex regulatory and general report requirements. Furthermore, most of enterprises have to comply with rules and implement BI tools to ensure legal compliance [1 p. 5].
On the other hand, enterprises need to implement quality management system (QMS) in order to improve and control all processes in the organization that will help to monitor and evaluate business operations and satisfy customers demand. Using the QMS, organizations manage their work in a systematic manner, where all activities are documented in accordance with the written manuals, procedures, instruction, specification and forms, which help to determine whether prescribed activities are accomplished successfully. QMS stores large volumes of information related to products and services that can be used to monitor the performance of the services and define actions to improve the performance, efficiency and accuracy of services. Decision makers have the necessity to have access to performance indicators to control and evaluate business processes. To access to the set of indicators about processes, there is a need to concentrate all information into a data repository, from where decision makers should be able to access indicators related to their business processes using simple, fast and easy tools that will help to define strategies and make decisions.

Considering the points mentioned previously in the context of the evaluation and improvement of processes across departments in enterprises, BI solutions reveal to be appropriate solutions. BI applications can be valuable tools to evaluate, monitor, control and audit all organization levels using Key Performance Indicators. Using BI solutions decision makers have the opportunity to access real time information, be provided with high quality reports and to achieve a level of maturity to implement multiple BI projects in the future.

In fact, Business Intelligence requirements are increasing and enterprises are depending on IT staff to fulfill these requirements. They usually depend on IT personnel to get requested BI reports. Business requirements can be inconsistent because they depend on economic impact, regulations and many other factors. Consequently, BI applications and models need to be changed and populated overtime in order to support new type of requirements and make new type of analysis. On other hand, business requirements changes very frequently overtime, and by this fact companies need different kind of management reports to overcome market changes and get advanced position against to competitors. In another point of view, IT staff needs time to develop new type of reports for business, however the managers or decision makers need to get the required report in a very short time, for that reason there is a need of “BI self service
tool”[1 p. 7], which will decrease IT support to a minimum level.

On the other point of view, Business Intelligence (BI) applications are composed by multiple tasks and components such as data integration, modeling, warehousing, OLAP, matrix creation and management, reports, dashboards, queries alerts and many more. When business requirements frequently changes overtime, implementing many component BI projects becomes hard and difficult. In this context, in order to simplify the implementation of BI projects, there is a need to use a kind of BI tool that has the capability to automatically update all dependent components when occurs changes in any single component [2 p. 4] Unfortunately not all BI tools have such kind of automatically components changing capability. According to Forrester [2 pp. 5-6] BI applications are classified into two categories: “first generation metadata-driven BI” and “second generation metadata-data driven BI”, where second generation BI systems are improved BI systems, which has agile and self service capability.

1.2 Problem Description

The Polytechnic Institute of Viana do Castelo (IPVC) is a high public educational institution providing opportunities for quality training in the human, cultural, scientific and technical sectors. IPVC integrates seven organizational structures, namely, five schools (Education School, Agricultural College, Technology and Management School, Management Sciences School, Health School), Social Services and Central Services.

Recently, the IPVC implemented a quality management system (QMS) in 2009 that allowed to ensure the ISO 9000 certification. QMS is used to perform daily services in the organized manner, covering the activities of the IPVC materialized in many processes, in particular, Academic, Environment, Health and Safety, Social Services, Courses Creation/Restructuration, Training, Economic-financial management, Management of works and Infrastructure, Information Management, Management and Improvement System, Project Management, Information Systems Management, Observatory, Promotion and Image, Human Resources and Technical and Educational Resources.

Nowadays, the QMS plays an important role in the management of the IPVC. In fact, the QMS can help managers to perform services effectively, as well as to define actions to improve it. In that context, top managers (and especially QMS managers) have defined a set of key performance indicators (KPI) in order to observe and evaluate all management processes to support decision making activities. The purpose of KPI is to get quantifiable measure, which reflects critical factors of success towards the institution strategy and goals. In the case of IPVC, the defined KPIs comprise the twenty-four processes covered by QMS of the institution departments, which are dispersed geographically. In this sense, IPVC has the need to integrate all data of QMS into one place that will help to define and evaluate institution work and to be eligible to compare current state with their strategies and goals. In fact, integrating all data across all the schools will give the possibility to get valuable information on how the work is performed by IPVC departments. The integration of all data across all the schools to produce KPI will allow to have an important tool to monitor IPVC activities. For the Institution, it is necessary and important to provide decision makers with tools that will permit to access KPIs on time, based on information produced by the QMS. KPI reports are vitally important for IPVC in order to monitor and analyze all services, activities, as well as to improve the performance objectives.

In that perspective, it is appropriate to study and explore the implementation of a Business Intelligence environment for the managers of the quality management system in Polytechnic Institute of Viana do Castelo. In this context, the motivation of applying BI application in the IPVC Quality Management System (QMS) is to develop a decision support system that will help to control, evaluate and improve IPVC educational performances.

1.3 Objective

The purpose of this project is to support quality management staff in decision making activities, in order to give opportunity to define and evaluate the institution services, compare institution strategies and goals and help in the planning of the future improvements. In this sense, the main objective is to implement a decision support system using BI technologies that will answer to the Key Performance Indicates (KPI) requirements. For this purpose decision makers need to access information about all the
processes of IPVC schools from one system to simplify and support decision making activities. Using business intelligence applications it is possible to satisfy business needs and QMS manager’s expectations, such as increase productivity of work and improve and optimize processes in educational institution. In this work we will consider and apply BI tools in order to develop a decision making system to answer to the KPI requirements specified by the QMS managers. For this purpose, we define the following objectives in the frame of our project:

- Develop a Data Warehouse system in IPVC, which will give advantages to integrate all IPVC QMS processes data into one common place and to achieve a maturity level to be able to develop various business intelligence projects in the future, depending on demands and necessities;
- Analyze integrated data and prepare analytical reports;
- Develop a decision support system for IPVC in order to support decision making activities;
- Develop tools in order to monitor and evaluate predefined Key Performance Indicators (KPI) to assess the state of education performance in a short period of time.

In the context of the decision support system, the objective is to create a Business Intelligence environment in a high educational institution. Within this project we will provide to the IPVC decision makers (or managers) with analytical reports in order to help and support right decisions making in a timely manner. To develop this project we will need to integrate all information about IPVC processes from different data sources into a single repository, called Educational Data Warehouse, which is suitable for direct querying and analysis, as well as to apply Business Intelligence tools to generate reports and dashboards using predefined Key Performance Indicators in order to observe and evaluate all management processes in a timely manner.

Taking into account the objectives of this work and due to time limitations and difficulties to involve QMS managers, the BI system in this project has only been fully implemented for some processes of IPVC. However, we consider that, despite these limitations, the project is a contribution to demonstrate the advantages and benefits to develop BI tools in a high educational institution.
1.4 **Structure of the document**

The thesis is composed of five chapters.

Chapter 1 introduces the project, the problem description and the purpose of this document.

Chapter 2 presents the concepts and objectives of Quality Management Systems (QMS) and ISO standards.

The next chapter is about Business intelligence (BI) concepts and its components such as operational systems, data warehouse, data analysis and reporting.

The fourth chapter is entirely devoted to implementation details of BI system for IPVC QMS. In this chapter we present business needs, the methodology used to develop the project, the data warehouse models and reports.

The last chapter of this document consists of summary and conclusions about this project and points future work as well.
Chapter 2 - Quality Management Systems

2.1 Introduction

Traditionally organizations move their activities by the need to produce high rates of performance, efficiency and efficacy, the satisfaction of their employees, customers and suppliers in order to be competitive and to enable organizations to face competition. The application of Quality Management Systems – QMS, particularly the ISO 9001 standard in organizations allows the definition of a set of processual and organizational documentation in order to guide and achieve high levels of efficiency, improve the services performance and to improve the internal and external quality of the services provided. In this sense, in the next sections we will describe shortly the objectives, the characteristics and the general benefits of the implementation of QMS in organizations.

2.2 Quality Management Systems Objectives

Quality Management System (QMS) is a set of coordinated activities, which guarantees a common attitude in the management of an organization and helps to control all processes in order to improve the efficiency and performance of the business. In organizations all rules are defined as policies, procedures, tasks, which are aligned into QMS functions with their objectives to help end-users to perform their daily work.

The objective of QMS is to satisfy business’ and customers’ requirements and at the same time, to extend the business operations outside of the company. QMS allows companies to present high rates of yield, by the satisfaction of their clients, partners or collaborators, and by maintaining high levels of competitiveness that allows them to face concurrency and assure their survival in the markets where they develop their activities. QMS includes many organizational processes and functions, which are interlinked between them in order to satisfy stakeholders and customers. In this sense, the main purpose of QMS is to increase customers’ satisfaction, credibility, and improve products and services quality [3].
The development of QMS documentation is achieved by defining quality standards and practices in order to monitor and review external or internal performance against the defined quality standards and practices.

The document structure of a Quality Management System consists of a set of documents, where is specified quality requirements, which are materialized through procedures, policies, structural matrixes and forms. With this information it is possible to define quality standards and identify and provide the best practices in order to monitor and review the efficiency and performance of the processes.

In general, organizations use QMS to manage their work in a systematic manner. As mentioned in Westinghouse Electric Company QMS document, “In QMS all activities are documented in accordance with written manuals, procedures, instructions, specifications and drawings that contain appropriate criteria for determining whether prescribed activities have been accomplished satisfactorily” [4 p. 5].

In terms of objectives, the QMS implementation in economical organizations and in educational institutions can converge for a set of goals [5]:

- To improve the quality of products and/or services;
- To use information and access it in timely manner;
- To optimize processes by providing automatic transmissions of requests between the users and services;
- To reduce execution time of tasks and answer to requests efficiently;
- To increase the collaboration between internal and external stakeholders by using centralized environments (for example web-based applications);
- To determine key indicators in order to evaluate and monitor services.

In general the Quality Management Systems that are applied to customer’s satisfaction must comply with standards of information systems requirements defined by credible institutions like the ISO (International Organization for Standards). This institution is recognized by providing a set of standards in order to improve the efficiency and performance in many areas of the companies, with the purpose to define guidelines and to develop more efficient, safer and cleaner products and services. Using the ISO recommendations, companies are able to be recognized as a reliable system,
which gives opportunity to increase chances to do business in worldwide more effectively [5].

One of that standards is the QMS ISO 9001 certification standard. It corresponds to a tool in order to achieve customer enhanced satisfaction. Implementing the ISO standards gives opportunity to obtain advanced management mechanism, which will allow to improve products and services to increase chances of success in the global competition. In a general point of view the ISO 9001 is a standard documentation of processes consisting of a set of process matrixes, procedures, work instructions, process forms, requirements and other kind of documentation related to processes [6]. In the next section we will present a general description about this standard.

2.3 International Organization for Standardization (ISO)

International Organization for Standardization (ISO) is a worldwide organization which develops ISO standards. These standards are developed in terms of voluntary technical efforts in order to improve the performance and efficiency of diverse types of business operations. The use of ISO standards gives the opportunity to improve all kind of business operations and to develop more efficient and safer products/services. ISO Standards safeguard users and consumers. Its related documents are divided into three main dimensions of sustainable development: economic, environment and social fields [5].

The work of preparing International Standards is performed through ISO technical committees, cooperating with international organizations, governmental and non-governmental bodies. However some companies provide certification services which are previously certified by the ISO technical committees, for example, SGS - Société Générale de Surveillance SA², APCER³, which belong to the IQNET (The international Certification Network) Association⁴.

The ISO 9000 is a family member of international quality management standards and guidelines. It is recognized in establishing effective and efficient quality management systems. In the field of Information Systems, ISO Technical Team 176 (TC 176 - see Appendix A) is responsible for the development of standards for quality

² http://www.sgs.com/
³ http://www.apcer.pt/
⁴ http://www.iqnet-certification.com/
management and quality assurance [5]. In this standard, the documents for Quality Management Systems are comprised by [5]:

- ISO/FDIS 9001:2008 - Quality management systems – requirements;
- ISO 9004:2000 – Guidelines for performance improvement;
- ISO 19011:2002 Guidelines for quality and/or environmental management systems auditing.

In other hand, the ISO 9000 provides the basic concepts of QMS based on eight quality management principles and is used to achieve processes with continuous improvement capability. These eight principles are: customer focus, leadership, involving people, process approach, systems approach, continual improvement, factual decision making, and mutually beneficial supplier relationships. The ISO process approach is illustrated in Figure 1. During the implementation of a QMS, there are five sections in ISO 9001 standard that indicate activities that need to be taken into account [5 p. 2]:

- Overall requirements for the quality management system and documentation;
- Management responsibility, focus, policy, planning and objectives;
- Resource management and allocation;
- Product realization and process management;
- Measurement, monitoring, analysis and improvement.

As we mentioned, the ISO 9001 specifies basic requirements for QMS, which are needed to provide products and services to enhance customer satisfaction and meet regulatory requirements. In practical terms, the application of the ISO 9001 requirements allows to achieve first level of QMS performance in order to develop high quality of products and fulfill customer’s needs and expectation.

After a system answers to the requirements of ISO standards, it can be used for certification, registration or contractual purposes in order to be recognized. One fact is that ISO 9001 Standard recognizes that “customers play a significant role in defining requirements as inputs” [7 p. 11]. QMS supports the monitoring of customer satisfaction, which is necessary to evaluate and validate whether customers’
requirements have been meet. The ISO 9004 version gives some guidelines in order to improve QMS by considering all involved parties interests and to extend the benefits obtained from ISO 9001. This version is used to achieve systematic and continual improvement of organizations overall performances.

![Figure 1 - ISO 9000 process approach](5 p. 2)

In terms of the control of the implementation of the ISO 9002 family, the ISO 19011 Standard is used for auditing the QMS and has guidelines and instructions on how the audit of management systems should be performed. During the performing of an audit, organizations need to ensure that QMS was implemented successfully and meet all the requirements, which were predefined in ISO 9001 or ISO 9004 standards. In companies, audits are performed by ISO 9001 Auditing Practice Group (APG) [8].

### 2.4 Applicability of Quality Management System

There are many good reasons why organizations must apply QMS into their systems, for example:

- To produce products with consistent quality;
- To improve their quality of services provided to clients;
- To improve companies’ management processes;
- To answer customer’s requirements of having a certification;
To monitor their processes and achieve great client satisfaction.

In order to implement a QMS in an organization, the top managers should define a set of quality policies, quality objectives and quality indicators. The quality objectives are measured using quality indicators which includes data availability, data quality and customer satisfaction. The ISO suggests some steps (or guidelines) to implement efficiently the standard [5 p. 4]:

1. Fully engage top management
   - Define the reasons why the organization wants and needs to implement ISO 9001;
   - Define the mission, vision, and values in the organization;
   - Define the organization’s stakeholders: customers, suppliers, stockholders, employees, society, etc;
   - Define the quality policy;
   - Define and align organizational objectives and related product/ service quality objectives
2. Identify key processes and the interactions needed in order to meet quality objectives
3. Implement and manage the QMS and its processes (using process management techniques)
4. Build the ISO 9001-based QMS, in special to:
   - Identify ISO 9001 requirements;
   - Map these requirements with the implemented QMS, where applicable;
   - Make a gap analysis: identify where in the organization the requirements of the existing system are fulfilled, and where they are not;
   - Include in the QMS processes the activities, procedures and controls needed.
5. Implement the system, train company staff and verify effective operation of the processes
6. Manage the QMS:
   - Focus on satisfaction of customers;
   - Monitor and measure the operation of the QMS;
   - Strive for continual improvement;
Consider implementing business excellence models in operations of the company.

7. If necessary, seek third party certification/registration of the QMS or as an alternative, issue a self-declaration of conformity.

2.5 **Benefit of Quality Management System**

In terms of the benefits of the QMS implementation in an organization, QMS enables to achieve the goals and objectives set out in its policy and strategy. According to Department of Trade and Industry document, “It provides consistency and satisfaction in terms of methods, materials, equipment, among others, and interacts with all activities of the organization, beginning with the identification of customer requirements and ending with their satisfaction, at every transaction interface” [9 p. 1].

The usage of QMS functions gives opportunity to have access to a set of key performance indicators that reflects the activities of the organization and, in this sense, it allows to monitor services performance. In the last years, many companies and organizations applied the ISO 9001 (and other) standards. In general, by the results achieved and mentioned in the literature, a good quality system can bring the following benefits:

- Set direction and meet customers’ expectations;
- Improve process control;
- Reduce wastage;
- Lower costs;
- Increase market share;
- Facilitate training;
- Involve staff;
- Raise morale.
Chapter 3 – Business Intelligence systems

3.1 Introduction

Day after day, managers need each time more information about the various business activities of their organizations, to take strategic decisions based on the information, which are located in the available business sources. Usually, the historical information of these organizations is stored in information repositories, on which analytic processing servers process all the possible analysis combinations, disposing fast response times to all possible queries that decision agents may post.

The Business Intelligence concept refers to a set of techniques, which can be used to help managers in their decisions in order to respond to business needs using information technology (IT) capabilities. In this context, the tools to analyze the business needs could be analytical reports in order to prospect new market needs, which have the objectives to timely respond to customers, manage customer satisfaction, increase profit, optimize business processes, among others. In order to develop a Business Intelligence system, the Information Technology (IT) structure could include operational systems, databases, data warehouses, online analytical processes (OLAP), reporting tools and other IT components. In this sense, using this kind of systems to analyze data with the purpose to deliver analytical reports, gives the opportunity to align IT to business needs. Additionally, the relationship between the IT capabilities with BI systems offers the possibility to provide organizations with advanced analytical solutions, which allow to improve business processes, increase satisfaction of business persons and be aware about the business competitive environment in terms of concurrency and challenges.

A Business Intelligence system relies on intelligence information which is used to support the effective decision making activities concerning production, marketing and personnel. “Effective decisions are choices that move an organization closer to an agreed-on set of goals in a timely manner” [1 p. 8]. The decision makers in this process could be top managers of the company, the chief executive officer (CEO), the president, chairpersons or others. The key of organizational success is to make good choices based on specific goals, measures, information and feedbacks.
In order to make effective decisions, in general, the high level managers of an organization consider the set of business goals to measure how chosen courses are moving toward to these goals. The information about business processes is based on these measures, which must be provided in a timely manner. Decisions are made based on “foundation information” about current business conditions and are evaluated after receiving the “feedback information” as a result of decisions [10 p. 9]. Figure 2 illustrates the concepts of effective decisions that consist of three keys: specific goals, concrete measures, and timely foundation and feedback of information.

![Figure 2 - Three keys for effective decision making](image)

Organization need to define measures to understand if their goals and objectives are achieved or not. As goals are more specific the measures could be defined more clearly and are more measurable. Measures are the result of decision processes and feedbacks in the company, they are used to evaluate and monitor business processes. For example, consequences of some decisions in a company could be sales increase or decrease and this information will appear automatically in defined measures. The feedbacks are inputs (sales increased, or decreased) from customers that affect organization as a result (value) of decisions, which are represented in measures. Business goals define the status levels of the measures, so if values are less than defined goal the decision is evaluated as a bad decision, and if it is more than or equal, then decision could be evaluated as a good decision, meaning that specific goals were achieved. In an educational institution a global goal could be “students’ satisfaction in alimentation process” measured by “percentage of meals served” in canteen with a goal of 80%, from where “percentage of meals served” is a specific goal. We can measure
decision rightness based on the increase or decreased of student’s meal service percentage in canteen. Table 1 is an example that shows decisions making support table.

<table>
<thead>
<tr>
<th>Global Goal</th>
<th>Specific goal</th>
<th>Measures (How we know our goals is reached or not?)</th>
<th>Foundation and Feedback Information</th>
</tr>
</thead>
</table>
| 1. students satisfaction in alimentation process | Maintain students number of meals served at canteen | Students meal served are 80% and more                | If enrolment are: 
|                                                 |                                                   |                                                      | >=80% ☺ 
|                                                 |                                                   |                                                      | < 80% ☹ |
| 2. Students registration academic service       | Increase students online subscription             | Students online subscription are 70% and more        | If Online subscription are: 
|                                                 |                                                   |                                                      | >=70% ☻ 
|                                                 |                                                   |                                                      | < 70% ☻ |

Table 1 - Decision making support table

Decisions determine the general course that organization is going to take in a defined period of time. Decisions point the organizations toward to its goals. The goals have the repeatable measures that are used to control process toward defined goals and determine whether the organization is making effective decisions.

3.2 **BI systems**

“Business Intelligence is the delivery of accurate, useful information to the appropriate decision makers within the necessary timeframe to support effective decision making” [10 p. 14].

Business persons have to make effective decisions on time, which must rely on trusted information from well designed measures. Business Intelligence application has the capability to provide business persons with feedback information about their business performances in a timely manner. The feedback information from customers has a vital importance for business persons to make effective decisions and to evaluate decisions at all organization levels. Business Intelligence delivers timely updated information, which significantly influences on decision making processes.
Business Intelligence has the capability to analyze huge volume of data. The exploration of data sources could reveal trends, correlations and dependences, but such kind of relations could be impossible to be noticed by human being using either layout-let (designed to get appropriate report) or led discovery (information we find determines, where we want to go next) [10 p. 16]. In Business Intelligence systems “highly sophisticated mathematical algorithms are applied to the data to find correlations between characteristics and events. This type of information can be extremely helpful in organizations when planning marketing campaigns, setting up cross-product promotion or doing capacity planning for the future, determining when additional resources and efforts would be produced for the most effective results” [10 p. 17].

3.3 Applying BI systems in companies

Inside each company decision makers’ activities can be classified into three levels [10 p. 18]: upper level decision makers, middle level decision makers and operational level decision makers. Figure 3, Figure 4 and Figure 5 present decision makers’ levels, measures and timing of the foundation and feedback information at each level of the organization. At different levels of management different type of Business Intelligence tools and techniques are required to approach predefined goals. In each level of management specific goals, concrete measures, timing of foundation and feedback information is required in order to make effective decision.

Figure 3 - Specific goals at each level of the organization [10 p. 18]
Upper level decision makers set long term goals, where measures that are defined are highly summarized. Highly summarized measures are also known as Key Performance Indicators (KPI).

Middle-level decision makers manage departments and organization at operational level. Middle level decisions are based on short term goals that are needed for planning to manage functional processes in organizations. Decision makers need to get reports about business activities and to apply drilldown techniques to the reports. Drilldown techniques are provided by BI reporting service that are used to obtain more detailed information and help to make better decisions.
Middle level management can also use data mining techniques effectively for making decisions.

Operational level decision makers (forepersons, managers, and group leaders) rely on day-to-day operational goals in order to manage daily information to react to changes. Based on the feedback information decision makers need to react quickly to improve processes on time.

### 3.4 Applicability of Business Intelligence

In general, the amount of information in organizations increases over time due to business processes. It is very important for enterprises to maintain and manage all information related to their businesses. In fact decision makers have the need to get complete reports about all business in a very short time. For that purpose, there is a need to have a system which will have the capability to access a variety of data sources (systems, databases, office programs, text files, web, etc) and to integrate all information into one common place. For such kind of advanced business needs, the solution can be provided by Business Intelligence (BI) systems. A BI tool gives the opportunity for decision makers to access all data, integrate them in a Data Warehouse (DW) and get analytical reports in a very short time. Figure 6 presents traditional business intelligence architecture with components that can be used to deliver solutions for business needs.

![Traditional Business Intelligence Architecture](image)

Figure 6 - Traditional Business Intelligence Architecture [11 p. 7]
The major steps to deliver timely BI reports for business persons are: extraction, transformation, loading, creating data marts with Online Analytical Processes (OLAP) and deliver BI reports. Extraction, transformation and load are related to data integration process (DI), which is performed by BI systems to allocate data into a DW as shown in Figure 6. To implement DI process it is essential to identify data sources. In BI systems, data is extracted from enterprise sources such as ERP, CRM, financial systems, databases, text files, among others. These sources may reside in different locations and on different platforms. After data is loaded into DW, BI systems apply OLAP techniques to generate Data Marts (DM) [12]. Using OLAP data is stored into small databases called Data Marts, which give the opportunity to generate various reports, to have fast access to data by specific groups and distribute information to remote sites. As shown in Figure 6, BI starts from data sources to support users in the process of analyzing very large quantity of information and delivers management reports. It generates semi or fully automatic reports in order to answer daily business questions [13 p. 5].

In an organization, the following steps should be performed to implement a BI project [14]:

1. Define data sources – In enterprises departments, data is usually stored in databases via applications;
2. Understand business needs – The identification and understanding of business needs will enable to construct DW and transform data to business information;
3. Create Data Warehouse - Define measures, dimensions and fact tables to create a data warehouse;
4. Make an ETL process – ETL process is used to store information into the data warehouse. BI tool can automatically import and transform data from different systems and different locations.
5. Analyze data and deliver reports – OLAP tool is used to store data in cubes from DW in order to analyze data. From cubes, reports are developed and distributed to decision makers.

These described five steps are the traditional path to develop BI projects. It enables to answer to business needs in enterprises by focusing on exploring and
delivering real time business information. BI has also the possibility to use predictive analysis tools, which helps to give recommendations to business persons using data mining techniques. For example, it allows to estimate the future growth of the enterprises according to its business types [14].

Business requirements often change overtime and depend on economic impact, regulations and many other factors. Because of that, BI applications and models need to be changed and populated overtime in order to support new type of requirements and make new type of analysis. For this reason, it is recommended to decrease reliance on Information Technologies staff [1 p. 2]. BI applications need to provide the ways for decision makers to fulfill their information requests related to their businesses via self-services.

New generation business intelligence applications have seven characteristics such as “access any data source, easy and accurate data visualization, see relationships, communication and collaboration, data in view all of the time, intuitive interface, desktop or server based” [15]. They have also self-services capability which uses five type of BI search: report search, faced search, NLP search, exploration engines and text mining [16] that gives opportunity to search and explore large volume of data. Next generation BI system provides with advanced reporting tools, which gives ability to get dynamic reports. Advanced reporting tools allows to type key words in natural language to find needed information in a very short time. New generation BI tools use advanced language processing algorithms, which gives opportunity to parse questions in common language into SQL standard language with the objective to query databases (Figure 7).

Finally, it should be noted that, according to Massachusetts Department of Elementary and Secondary schools [17 p. 6], BI can bring a set of benefits in educational institutions, which include:

- To provide decision-makers with the meaningful information on what is working and what is not in education processes according to student attendance, grades, test scores, observations, disciplinary actions, and more;
- Efficiently examine performance over time at multiple levels: student, class, grade level, school, and district.
• Easily aggregate and disaggregate data, compare disparate data, and produce customized reports, providing more detailed and insightful information through the data analysis process (Figure 8).

Figure 7 - Self-Service BI application [18 p. 5]

Figure 8 - Massachusetts DW - clarifying questions through the data analysis process [17 p. 6].
3.5 Key Performance Indicators (KPI)

The objectives of key performance indicators (KPI) are to better evaluate organizations current business conditions and to help in planning the future. KPIs are used to measure business progress toward organization strategy and goals. Each KPI is a high summarized measure which is used in upper level of decision making. Decision makers define long term goals based on organizations strategy and mission which are not often changed. KPIs definition takes into account detailed goals and measures, which will reflect organizations most vital aspects. Measures represent a status indicator, showing whether these measures are within an expectable range [10 p. 19]. In the case of an educational institution, KPI could be: students’ online subscription, accommodation occupancy rate, student’s accommodation satisfaction, alimentation service, among others.

Key Performance Indicators (KPIs) are frequently used in dashboard reports in order to improve strategic and decision making activities. A Business Intelligence system can provide organizations with digital dashboard reports which are used to help executives and decision makers to make decisions better and faster [19 p. 3]. It enables decision makers to establish measures and criteria that are used to monitor and evaluate all business processes at a single glance in all level of the organization. Dashboards are based on Key Performance Indicators (KPI) measures and can include business values, goals, status and trends [20 p. 212]. Business intelligence usually gives the capability to create dashboard reports which are composed with KPIs components using visual graphical images such as stop light, gauges and other symbols. Dashboards reports provide the necessary status information about business trends at a single glance. Using dashboards in decision making activities, decision makers are able to evaluate organizations health and correct problems on time. Dashboard reports are also useful to determine how the organization moves towards specified goals. Figure 9 shows a digital dashboard report example, where we can see values, goals, status and trends of KPIs.

All processes which influence organizations businesses could be captured in dashboards. This feature distinguishes dashboards from other reports as an effective management tool for measuring, evaluating and monitoring all organization levels in order to compare performance with defined goals. The KPIs types depend on the nature of the organization and organization’s strategy.
3.6 **Operational Database**

Operational databases are used to store daily transactional data during business processes. The usage of operational database systems allows the management of data in an organized manner. Operational databases are also called transactional databases or Online Transactional Processes (OLTP). According to Larson [10 p. 26], “OLTP systems are embedded into the applications and front users are able to manage their data by inserting, editing, deleting, updating, filtering, summarizing and reporting”.

There are several kind of databases such as row oriented, column oriented, object oriented, among others. From them, row oriented relational database management systems (RDBMS) are mostly used in applications to support OLTP, which are data source systems for BI tools and data warehouses [21 p. 13].

In databases, similar and logically connected data are grouped into subjects called data entities or tables. These data entities/tables have relationships between them, which form the relationship model, that’s why these systems are called Relational Databases Management systems (RDMS).

In RDBMS tables consists of a set of attributes [22 p. 25] also called fields, which defines what kind of data can be stored. The data which is stored in the fields are called tuples or records. Table must have a unique name and fields have a name and type, where type specifies what type of data can be stored and name gives a way of accessing. Each table must have a primary key that identifies each record. The relationships between tables can be established using reference keys. Reference key means that a table has a Foreign Key [22 p. 315] that is a field or a combination of fields whose values match a primary key of another table.
Figure 10 represents an example of a relational model of OLTP system. We have four data entities - Class, Student, Presence and Lesson that are related to each other. Table Class has one attribute Class_id, which is the Primary Key. Tables Student and table Lesson are related to table Class using Reference key.

Database systems have data query tools that use SQL (Standard Query Language), and are used to retrieve information from databases using the relational model of the databases [22 p. 20]. With Data Query Tool we can manipulate data from databases in order to retrieve appropriate information, make summary of data, get reports, edit, delete, update and transfer data into other database systems.

3.7 **Data Warehouse systems**

“A data warehouse is a subject-oriented, integrated, time variant, non-volatile collection of data that serves as a physical implementation of a decision support data model and stores the information on which an enterprise needs to make strategic decisions” [24 p. 2].

Data Warehouse (DW) platform consist of hardware servers, operational systems, database management systems and storage infrastructure [25 p. 6]. Data
Warehouses concepts can be used in any kind of business fields. They can be used in manufacturing, educational institutions, tourism industry, among others.

OLTP systems are used as data sources for data warehouses (DW). The objective of a DW is to collect and integrate all data across different systems and locations and locate them into one source. From the transactional databases we can store large volume of data in a DW, in a central, manageable, analytical, governable location, from where we can get summary reports, which will help to support decision making processes [26 p. 33]. Allocating the data into a DW from multiple data sources is the result of integration process, with the purpose to have accurate information in a timely manner.

Data warehouse models includes business entities like customer, product, finances and functions like sales, supply chain, operations, which represent whole enterprise performance. The data which will be stored in DW will be historical, read-only data.

The process of storing data from transactional databases into a data warehouse is called ETL process, which means Extract, Transfer and Load [10 p. 30]. ETL process has the objective to collect data from diverse sources and to aggregate it into a dataset to provide DW with complete, trusted data [27 p. 9].

A data warehouse consists of dimension tables and fact tables. In dimension tables data is stored by subject. Fact tables are connected to dimension tables from where they take quantitative/qualitative values. For example students name, address and phone number could be stored in students dimension table. From dimension tables, data are populated into fact tables and measures are calculated.

A measure, also called a fact, is a numeric quantity which expresses some characteristic of organizations performance. The information that this quantity represents is used to support or assess the performance and decision making of an organization [10 pp. 30-31].

Numerical measurements are stored in fact tables which are taken from the intersection of dimension tables [28 p. 12]. For example, students’ subscription number across schools, locations and time could be a numerical measure in fact table, where schools, location and time are intersection (dimensions).
The creation of a data warehouse is a preparation step in order to use business intelligence systems. To analyze data, it is better to run BI systems over DW than over OLTP systems. The reason is that the use of a DW allows to have complete, integrated and historical information and at the same time, the system is independent from transactional processes. In fact, if we use a transactional database to analyze the data whilst there are a lot of transactions, there is the possibility that the system will halt and overload.

The most usual process to create a DW system is to use a database system such as Relational Database Management System (RDBMS). To create a data warehouse there is two possible data models: Star and Snowflake models. They are based on relational database concepts and are composed of dimension and fact tables. In star model each dimensional table is directly connected to fact tables. Figure 11 is an illustration of DW star model.

![Figure 11 - Data Warehouse Star Model](29 p. 19)

On the other hand, snowflake model is based on hierarchies. “A Hierarchy is a structure made up to two or more levels of related dimensions. A dimension from the next at an upper level of the hierarchy completely contains one or more dimensions lower level of the hierarchy” [10 p. 35]. In Snowflake model each level of a hierarchy is stored in a separate dimension table and they are connected to fact
tables thought the up hierarchy dimensional tables. Figure 12 illustrates a DW snowflake model.

Figure 12 - Data Warehouse Snow Flake Model [29 p. 20]

The use of a data warehouse gives the opportunity to deliver solutions quickly, and allows enterprises to be mature and be ready to provide data for new solutions. With extended, growing and customized capability, DW allows to develop multiple new BI solutions and be mature to answer new type of business demands in the future [25 p. 8]. In fact, according to Massachusetts Department of Elementary & Secondary Schools [17 p. 5], Data Warehouse can bring a lot of benefits to educational institutions, like:

- Time saving in making decisions;
- Being able to access real time information on time in order to improve educational performances;
- Data warehouse can be used to aggregate and disaggregate data and produce customized reports;
- Integration and transformation capability to allocate all data about educational processes in one common place for future use.
- Historical perspective.
3.8 **Online Analytical Process (OLAP)**

BI application offers analysis services tools to analyze business data. This process is called Online Analysis processes (OLAP). OLAP tool use a cube structure, being data extracted from data warehouse and loaded in cube. OLAP has multiple features such as Key Performance Indicators to monitor business processes, Multidimensional Expression (MDX) to get analyzed information for reports and Unified Dimensional Model (UDM) which enables to slice-dice and get summarized information.

After the execution of data integration process, which loads data into a DW, it is possible to apply OLAP tool to analyze integrated data. To analyze data, OLAP uses multi-dimensional data cubes retrieving information from measures, dimensions, hierarchies and cubes [10 p. 39].

OLAP cube consists of cells which store summarized data called measures. Dimensions divide a cube into sections. Each tuple in OLAP cube is associated to hierarchies. Hierarchies are dimension levels which are also defined in cube [10 p. 284]. Figure 13 illustrates an example of a data cube.

![Figure 13 - A data cube example.](image)

In OLAP cube it is possible to calculate measures and navigate through the cube using MDX expressions and functions. Calculation can involve a number of different fields from different tables. In OLAP calculations are performed using Multidimensional Expression language (MDX). For example, in OLAP, KPI could be developed using MDX expressions for dashboards reports, which could be used to
calculate the KPI values, goals, current status and trends in order to compare values with business rules.

OLAP tool gives the ability to use several useful operations such as:

- Roll-up - taking the current data objects and doing further grouping by one of the dimensions;
- Drill-down - The drill-down operation is the opposite of roll-up. It navigates from less detail data to more details;
- The slice operation performs a selection on one dimension of the given cube, resulting is a sub-cube;
- The dice operations define a sub-cube by performing a selection of one or more dimensions;
- Pivot (Rotate) - Pivot is a visualization operation that rotates the data axes in view in order to provide an alternative presentation of the data. It allows visualization of the other side of the dice.

3.9 BI Reports

The main purpose of BI tools is to deliver reports to decision makers. All the strike of BI is to create high quality reports in a timely manner. BI reporting service enables the distribution of reports throughout the organization in a timely manner using Information Technologies (IT). Reporting service are composed by multiple programs, has series of services, web applications and databases, that work together in order to create a report management environment. BI uses data marts from the analysis service (shown in Figure 14) to develop web based or local reports. Analysis service allows to access data with external applications to develop reports that could be used in different applications like spreadsheets. BI report services allow to provide users with reports in most appropriate formats, since it is in general possible to produce different kind of report formats such as HTML, PDF, TIF, among others.

Reports can be constructed using SQL (Query relational database), MDX (Query Multidimensional Databases) and DMX (Query for Data Mining). These queries are used to extract data from defined sources and to provide these data to reports. Once the report is developed, it can be deployed in a report server. End-users can interact with
reporting servers indirectly through the use of Web Services. Reporting server responds to web services requests to deliver the report. Delivered reports from BI systems usually give the ability to execute operations like drill down to access detailed information if needed. It is common, that the delivered BI reports use a web-based environment, which gives the possibility to make the reports available in one common place, so that end-users are able to subscribe and access reports from a website. It is also possible to share reports through the network service. BI reports could also be subscribed and be emailed to users.

![Figure 14 - BI Report Service](image)

3.10 Business Intelligence Vendors

Nowadays there are many BI tools available on the market, which are successfully used by enterprises and companies to support decision making activities. Below we present a list of some BI tool vendors:

• IBM Cognos, http://www-01.ibm.com/software/data/cognos/
• Endeca, http://www.endeca.com/
• Attivio, http://www.attivio.com/
• Composite software, http://www.compositesw.com/
• Maia Intelligence, http://www.maia-intelligence.com/
• SAS, http://www.sas.com/
• Teradata, http://www.teradata.com
• Talend, http://www.talend.com/
• UC4 Software, www.uc4.com
• Microstrategy, http://www.microstrategy.com/
Chapter 4 - BI System Implementation in IPVC

4.1 Introduction

The Polytechnic Institute of Viana do Castelo (IPVC) has implemented its Quality Management System (QMS) in 2009 in order to perform its daily work in an organized manner in terms of decision making tasks as well as to perform the costumers’ services. The implemented QMS covers twenty-four processes of its departments. On the other hand, IPVC decision makers have the necessity to achieve quick access to integrated information about all processes that can be used to support decision making activities. Traditionally, IPVC managers based their decisions and tasks to evaluate schools work (in special services) and to be able to monitor in a timely manner all processes, which will help to act and improve educational processes on time if they discover that the processes state do not align with defined strategies and goals. For this purpose the decision makers of the IPVC have defined a set of Key Performance Indicators (KPI), which will represent the state of each process. The possibility to obtain KPIs will permit to decision maker persons to be able to control and manage the services performance. To support these needs and answer to IPVC decision makers requirements, we apply a business intelligence application over IPVC QMS. The objective is to use Business Intelligence application to increase productivity of work and to improve and optimize processes in IPVC.

In this project we want to study, explore and implement a business intelligence environment for Quality Management system of Polytechnic Institute of Viana do Castelo in order to help and to support decision making activities in the institution. We implement IPVC BI project with SQL Server 2005 technologies to answer to the QMS Key Performance Indicators requirements. Through the use of BI tool, we develop an educational data warehouse (EDW) in SQL Server Database with the purpose to integrate data of all twenty four processes. As the data about IPVC processes were spread in different locations, sources and systems, it was vital to allocate all data into a single data repository to integrate all internal and external processes information into one source. Then we were able to analyse the information from EDW with OLAP tool.
using Analysis Service, and finally we developed KPI reports to monitor and evaluate IPVC processes and support decision making activities.

In order to develop this project we choose to use Microsoft SQL Server 2005 software, which is considered a modern analytical BI tool and a growing data warehousing platform [31]. SQL Server 2005 has all the components which are necessary to develop BI projects in a single application. It allows to integrate data using Integration Service, to analyze data using Analysis Service and to develop reports using Reporting Service. All these services are located in a single user friendly application that SQL Server 2005 provides. SQL Server 2005 components have close relationship to each other so that when changes occur in one component, they are reflected in all dependant components. In this project we also decide to try to use another BI tool to deliver the reports to decision makers. We choose to use Tableau software to be able to develop next generation BI reports. With Tableau BI tool we connect to analysis service cubes in order to get data source and to develop high quality reports with a high level of interactivity enabling users to easily navigate and explore information.

4.2 IPVC and Quality Management System

The IPVC has implemented a QMS that covers the activities of seven organization units that includes schools, Social Service and Central Service. As an Educational Institution the IPVC provides opportunities for quality training in the human, cultural, scientific and technical sectors through its five schools [32]:

- Escola Superior de Educação (ESE) - Teacher Training College
- Escola Superior Agrária (ESA) - Agricultural College
- Escola Superior de Tecnologia e Gestão (ESTG) – School of Technology and Management
- Escola Superior de Enfermagem (ESEnf)– School of Nursing
- Escola Superior de Ciências Empresariais (ESCE) – School of Business Studies

The IPVC Quality Management Systems (IPVC – QMS 2009) [32] complies with ISO 9000 certification standard requirements and covers the following units process [32]: Academic Service, Environment, Health and Safety, Alimentation,
Accommodation, Scholarships, International Cooperation, Creation/ restructuring of Courses, Planning, Implementation and Evaluation, Supply, Heritage, Accounting & Treasury, Dispatch and Archive, Document Management, Management and Improvement System, Management Contracts and Infrastructure, Project Management, Management Information Systems, Observatory, Graphic Production and Audiovisual, External and Internal Communication, Human Resources, Library and Management of Education Space. The Quality Management System of IPVC also complies with COBIT (The Control Objectives for Information and related Technology) requirements following the policies and good practices for IT security and control. The following information is included in the IPVC QMS [32]:

- Process matrix;
- Procedures and work instructions;
- Forms;
- Data sheet occurrences;
- Other important documents and processes.

4.3 IPVC QMS Process Description

IPVC QMS are composed with twenty four processes of its departments. All these processes were explored and analyzed to be able to apply BI approach in order to answer to the defined business requirements. These twenty four IPVC processes are:

- Academic Service process
  Computer Application of Academic Management System manages all academic service processes. It tracks all educational records (in paper and digital forms) and generally include documentation about admissions, students registration, enrollment in classes, grades, graduation and more which is related to Academic Service responsibility.

- Environment, Health and Safety process
  QMS system manages all processes which are related to environment, health and safety in IPVC schools. The system tracks all the information associated to environment, health and safety processes such as simulation in schools, complaints, number of books and tutorials, staff and others.
• Social Service sub process – Alimentation
QMS manages all processes which are related to alimentation process in IPVC schools, the system records information about student enrollment in alimentation system and food orders, food supplement and other services which are done during the alimentation process.

• Social Service sub process – Accommodation
Academic accommodation service is a process which is composed by a sequence of tasks related to accommodation processes. The system manages the following accommodation services: booking rooms, maintain accommodation environment for customers (students, teachers, and other institute member) and satisfy accommodated persons.

• Social service sub process – Scholarship
Social Service system manages scholarship processes and records all the information related to scholarship. System records the following processes: scholarship interviews, responds, improvements, denials and others which are related to getting scholarship.

• International Cooperation process
IPVC QMS manages all processes related to International Cooperation which includes establishment of protocols and agreements with partners, sending and receiving students and teachers, scholarship transfers and other information which is related with international cooperation processes.

• Process of Course Creation / Restructuring
Process of course creation and restructuring is being managed by QMS of IPVC in order to simplify work during schedule restructuring and course planning. The process includes: proposal and restructure of courses, course validations and other information which is related with course creation and restructuring process.

• Formation process – Planning
IPVC QMS manages schools’ planning process which is related to application fees, submissions, schedules preparations, planning of programs and proposals to produce and also includes other tasks which are associated with IPVC planning process.
• Formation process – Implementation and Evaluation
Implementation and Evaluation process in IPVC schools is managed by QMS of IPVC. They use QMS to perform their task such as evaluation of teaching activities, report submission, conducting surveys, grade mobility, and other activities to evaluate IPVC schools work.

• Economic and Financial Management – Supply process
In IPVC schools economic and financial department uses QMS to manage supply process in schools. It helps to integrate business partners to achieve new level of efficiency and productivity. QMS tracks all information which is related to supply process: supply producers, supply fees, stocks management, materials, proposals, supplier’s contracts/breaks and more.

• Economic and Financial Management – Heritage process
QMS of IPVC manages heritage processes in schools by tracking the information into the system about conferences which is held in schools, storing information about physically existing assets, documented and undocumented goods, preparing heritage documentations and others related to this process.

• Economic and Financial Management -Accounting & Treasury
QMS of IPVC manages accounting and treasury processes in schools. It tracks all information about changes in budgets, monitor- purchased software’s in schools and analyzes revenues and commitments.

• Information Management – Dispatch process
QMS of IPVC manages dispatch process of IPVC schools and tracks information about complaints done by telephone or in person.

• Information Management – Document Management process
QMS manages document management process and tracks information related to compliance with regulatory requirements in schools.

• Management and Improvement System
QMS of IPVC manages IS management and improvement process. It tracks information such as identified occurrences, performed and planned systems audits, achievement of quality, questioners and satisfactions, among others.

• Management contracts and Infrastructure process
QMS helps to manage the work in schools which is related to management contract and infrastructure in schools. QMS tracks information about planned and executed tours, schedules and more.

- **Project Management process**
  QMS performs all work which is related to project management process in IPVC schools. System tracks all the information related to project management performance, planed/undertaken activities, execution and reprogramming of applications, funded and approved IT project.

- **Management Information systems**
  QMS of IPVC manages processes of Management Information Systems in IPVC schools by tracking the following information: requested and inadequate conducted trainings, occurrences of application server software, time of components recovery, incidents types, backups, critical data and much more which is relating to management information system process.

- **Observatory process**
  QMS of IPVC manages observatory process in schools and records information about validated and invalidated questioners, companies and institutions surveys and other information related to IPVC schools observatory process.

- **Promotion and Image - Graphics Production and Audiovisual process**
  QMS of IPVC is used during graphics production and audiovisual process. It records the information which is related to this process such as recording information of studies complaints, submission of complaints and works conducted across the schools and courses.

- **Promotion and Image - External and Internal Communication**
  QMS of IPVC manages external and internal communication processes in schools. QMS records the information related to this process such as disclosure of achievements, approvals, proposals, satisfaction, trainings offered, consultations/portals details, publications and other information related to external and internal communications in schools.

- **Human Resources process**
QMS of IPVC manages human resources process in schools. It records information about dossiers of individuals, employee’s details, training hours and more which is required by human resources process.

- **Library Process**
  Library process is about helping students, faculty and staff by understanding their needs and providing books and catalog of online available resources offered by library systems. Library process has Student registration service for borrowing and returning books, and to register complaints. They also have internal processes between the libraries, to exchange resources and enhance their work in order to increase the satisfaction of library customers.

- **Education Technical Resources - Education Spaces Management process**
  IPVC Quality Management systems is used to perform management of educational spaces in schools by recording level of satisfaction during questionnaires, requests for spaces, capacity of spaces and other information which is related to management of education spaces.

### 4.4 Using Agile BI methodology

Business requirements are consistently changing in global market and it is difficult to predict what business requirements will come tomorrow [33]. Therefore business persons do not know what business needs that they will have tomorrow. They only know what they want today. Even if they know what they want, they often change their minds. In this case, there is an advantage to apply an agile methodology (reacting quickly on changes) in BI development.

The Agile BI methodology consists of five life cycle implementation steps: story conference, task plans, development, sprint demo and retrospective [34 p. 9]. These steps are iterative and helpful in project implementation. The advantages of this methodology are:

- Understanding correctly business requirements;
- Appropriate respond to changes;
- Simplicity;
- Satisfy early and continuous delivery of valuable software;
Least effort and delivery of the project in a short time.

In the context of this project we decide to use an agile methodology, by the fact that other methodologies in general are inappropriate when requirements change quickly and BI projects do not work well when using standard software development lifecycle [34]. The option to use Agile BI methodology was very useful and helpful to start the project implementation effectively and to make the development process simple.

For the development of this BI project, we divided implementation tasks into five steps, which were frame in time boxes as suggested by TDWI’s (The Data Warehouse Institution) webinar - “Developing an Agile BI Environment” [34]. IPVC BI project processes were developed and deployed through the execution of the five steps defined in methodology (story of conference, task plans, development, sprint demo and retrospective), which were panned and scheduled in time. Figure 15 illustrates the IPVC BI project agile methodology steps.

In order to implement the BI system, the first step was to investigate and explore IPVC schools’ twenty four processes to understand KPI requirements. The KPI requirements were a starting point to decide how data warehouse should be modeled and this modeling was done in a top-down approach. So, KPIs were a guideline which was used as a source for the implementation of the project.

Following the Agile BI methodology, we start from the story of conference step. We get the requirements (KPI list) of the twenty-four processes. The completion of this step took a lot more time than originally planned as we faced some problems and difficulties to get and understand KPI requirements list from QMS managers. Then, we chose three processes from KPIs requirements list: 1. Academic Service process; 2. Environmental, Health and Safety process; 3. Alimentation process.

In the task plan step we define technical tasks and its plans on the paper to implement the chosen processes. According to the three process KPIs list, we define star models (dimensions and fact tables) to implement the DW. Then we establish task plans to implement the project and answer the business requirements. In the execution of this step, we faced some problems to clarify the defined KPI requirements that were sometimes general and ambiguous, due to difficulties to get access to right persons in QMS department. For that reason Task Plan step took a lot of time to define fact tables, measures, dimension tables and relationships between them for each process in order to
be able to calculate defined KPIs. After this step, we were able to create our DW model in the development step.

![BI Agile Methodology Life Cycle](image)

Figure 15 - BI Agile Methodology Life Cycle (adapted from [34])

In the development step we began to develop and deploy our project with the selected BI Tool. Our task plan document was used as a guideline in this step. We also made self monitoring of our work. Following the task plans we construct the DW and develop and deploy BI application. We use OLAP tool to generate the multidimensional structure materialized as a cube according to the defined measures and calculations that are used to answer the KPI questions. Next we develop reports in Microsoft Excel and web based environment to deliver them to decision makers.

In sprint demo step, we prepared a demo version of our project in order to present results to QMS managers. This demo version was used to allow users to check and validate if results are acceptable and what they really require and need. To support the validation process we create a validation document, which includes the KPI requirements, DW model, report in Microsoft Excel format with charts and web based reports. At the same time, in this step, we evaluate performed work during our development cycle in order to optimize next processes. The evaluation of project development cycle was helpful to perform next lifecycle processes more effectively.
It is noteworthy that the used methodology considers one day of work to present and validate the demo version, but in our case iterations for validation took more than two or three weeks. Indeed, as the project was not coming from top managers, there were difficulties to execute some steps that require the availability of managers to participate in working sessions.

Finally, in retrospective step we evaluate the correctness on how our last development cycle went, in order to improve next processes lifecycles and we began the next important business KPI requirements and start the lifecycle again.

Following this “Agile BI” methodology we develop and deploy all twenty four processes of IPVC schools. Unfortunately we were not able to validate all twenty four processes. We could validate only some of the processes. In fact, during the implementation of this project, we faced several difficulties that hampered the development of the final BI system, namely:

- General and ambiguous KPI requirements list which have created difficulties in the definition of DW;
- Communications problems – There was some difficulties to communicate with QMS persons in English in order to clarify KPIs;
- Time – We have to implement the project in a short time period;
- Limited human resources - The project was very huge and complex to be fully implemented by one person;
- Availability problems – The IT project was not requested from the top managers, which had resulted in difficulties to be able to schedule meetings with QMS person;
- In particular decision makers have not been directly involved in the project development cycle, which created difficulties to execute the validation process.

4.5 Selected BI Tools

To implement the IPVC BI project we choose SQL Server 2005. The selection of SQL Server 2005 was based on several reasons. First, SQL Server 2005 meets the needs and requirements to develop the project. Second, considering that most of technological solutions implemented in IPVC are based on Microsoft technologies, this
option can facilitate the use of SQL Server and its integration in IPVC information system. Finally, this option was also due to time limitation for the execution of the project and considering that it was more important to focus on having a final solutions rather than in testing capabilities of different solutions.

Microsoft SQL Server 2005 provides all aspects of Business Intelligence and has the following services [10]:

- **Integration Service** – known as Data Transformation Service (DTS). It has the ability to integrate all information across the organizations units into one source (Data Warehouse) in timely manner.

- **Online Analytical process (OLAP)**. It is the tool which is used to analyze data to make reports. OLAP provides aggregate functions such as count, sum, minimum, and maximum, among others to develop appropriate measure groups in OLAP cube.

- **KPI (Key Performance Indicators)**. This tool is used in OLAP cubes to develop digital dashboard reports, which will help decision makers to evaluate and monitor organization processes faster and support decision making activities. KPI could be classified in different status levels which can be, for example, very good, good, fair, bad or very bad. To classify indicators, the limits for each status level should be defined, in order to be able to identify business conditions at a single glance on digital dashboard.

- **Multidimensional Expression (MDX) queries and scripts** are used to get information from analysis services cubes and allow to make calculations, get measures and to develop reports.

- **Unified Dimensional Model (UDM)** allows to slice and dice and summarize information by demand and to present information in a meaningful manner.

- **Data mining tools** are used to find and present patterns and behaviors, which might not otherwise be found in the data.

- **Reporting Service and Microsoft Business Intelligence accelerators** are used to facilitate the delivery of information to decision makers through the entire organization. In SQL Server 2005, report services are created using business intelligence development studio and Visual Studio 2005 tools.
During our research we attended The Data Warehousing Institute (TDWI)\(^5\) webinars that introduced participants to various next generation BI systems and solutions. From the various solutions that demonstrate a number of interesting features, we consider that it could be advantageous to analyze the possibility to use Tableau software reporting solution in IPVC, since Tableau software offers a set of features that seems to be useful to be used in order to improve and enhance this project. Furthermore, Tableau software was selected as winner of 2010 CODiE Awards for “Best Software Development Solution” [35]. With Tableau it is possible to access all major data sources including text files, Excel, Access, SQL Server, SQL Server Analysis Services, Oracle, DB2, MySQL, PostgreSQL, Firebird, Netezza, Intesystems Cache, Hyperion Essbase, Teradata and Vertica [36]. Furthermore, Tableau allows to integrate multiple databases. Through the connection to different data sources we are able to develop different kind of graphical reports that Tableau software provides. These reports are very dynamic, allowing users to make operations such as new calculations, filtering, grouping and accessing the data, which gives “self-service” opportunity to deliver BI reports and reduce IT staff involvement. In fact, using the Tableau software, users are able to use self-service functionalities to develop new kind of measures for the reports without IT person’s involvement. On the other hand, Tableau software does not provide instruments to develop data warehouses, but it is oriented to access all major kind of data and to deliver very high quality reports. For that reason the use of SQL Server 2005 reveals to be a good solution to make data integration and data warehousing to integrate all data, while Tableau can be used to develop advanced reports to support decision making activities. Tableau reports could be published in Power Point, PDF and in other applications format or in web format using Tableau Server service, where end-users could get extremely dynamic reports.

### 4.6 Implementation

To develop this project, we had to execute a set of steps for each QMS process in order to implement a solution that will respond to the KPI requirements defined by QMS managers. In the following sections, we present a description of the steps that should be executed to deliver KPI reports to decision makers.

\(^5\) [http://tdwi.org/](http://tdwi.org/)
4.6.1. **Data Source**

In order to implement this project we should have access to three sources of information: data of IPVC Quality Management System (QMS), forms and the KPI requirements list. Lamentably, for reasons beyond the project we were unable to get data from IPVC QMS. Due to this fact and in order to be able to execute the project, we rely on the Key Performance Indicators (KPI) requirements. In order to overcome the unavailability of data to develop the project, we decide to generate some random data to populate the data warehouse with the objective to validate our implementation.

4.6.2 **Educational Data Warehouse (EDW)**

The development of the project has resulted in the definition and creation of an educational data warehouse model of the twenty-four processes. Figure 16 presents a partial view of IPVC DW model which is prepared to store data of IPVC processes.

![Figure 16 - IPVC Schools Data Warehouse Model](image)

This DW will be used to create cubes with the OLAP tool for further analyzing and report delivering. The IPVC DW is composed by 79 fact tables and 108 dimension tables. Because of this huge number of data entities and relations between tables (dimension tables and fact tables), we decide to divide and present the final DW model into smaller models corresponding to each 24 processes in order to facilitate the
presentation of our work and to demonstrate how KPI requirements have been answered. Each DW model is represented with all dimensions tables which are involved in each process in order to facilitate the interpretation of each model. However in the final EDW model, there exists only one table for each dimension, like, for example time dimension, student dimension, among others.

4.6.3. ETL (Extract, Load, Transform) process

After we define and construct the DW model considering the KPI requirements, it is necessary to load data from IPVC QMS into DW in order to do calculations and support KPI requirements. For this purpose, we should perform Data Integration (DI) process, which includes ETL (Extract, Load and Transform) tasks. However, as referred before, we were unable to have access to data sources of QMS. As it was not possible to get data source of the processes from IPVC schools and in order to validate our work, we generate random data in Microsoft Excel to be loaded in EDW. However we consider that this situation does not invalidate the developed work, as project objectives was to develop a decision support system for IPVC, and it will be possible in the future to create the ETL process to load data from IPVC QMS data sources. Nevertheless, for the purpose of our work, we have analyzed the steps that are involved in the creation of an ETL process using SQL Server Integration Service (SSIS) tool (Figure 17). SSIS is a graphical tool that can facilitate the definition of an ETL process. Traditionally data integration process involves the following steps:

- Extraction of Data

In order to build ETL process the first step involves the extraction of data from the data source. Data extraction process involves the identification and selection of data for transformation. The data selection task is used to access data for selection purpose establishing a connection to databases or files. The SSIS tool is used to establish a connection to data sources and extract data for the transformation purpose. In order to make data selection, when it is necessary to select data from various tables at one time, we need to define a SQL-Query command to access several entities taking into account relationship between data sources. After the connection to data sources is successfully established we can
make data selection. It could be done using SSIS package item in Data Control Tab.

- **Transformation of Data**
  Selected attributes must comply with DW requirements and be suitable, otherwise data will not be delivered to data warehouse and destination errors will occur. The transformation step involves operations like the conversion between data types of different databases systems used in data sources and DW.

- **Load of Data**
  After data is transformed into required format, we can load data into data repository.

  Figure 17 represents a possible ETL process for academic service using the SSIS tool of SQL Server, allowing to define all steps involved in a ETL process to load data to the DW.
  
  Figure 17 - Example of Academic Service ETL process

4.6.4 **Online Analytical processes (OLAP) Tool**

After data is loaded into Data Warehouse, we move data into OLAP cubes to analyze information and develop reports. With OLAP tool we can easily store the data
into cubes. It gives the opportunity to construct cubes based on dimension tables, fact tables and to build hierarchies with multiple levels. In some applications, OLAP tools (for example Microsoft Visual Studio used in this project) include a cube designer which allows to define dimensions (used to summarize values) and measures (the values to be aggregated) to generate the multidimensional structure. These tools permit to define general aggregations functions such as sum, count and average to define measures, or to define more complex functions using MDX commands. Figure 18 presents an example of the cube designer interface with the definition of measures and dimensions in the case Academic Service process.

![Cube structure interface](image)

In order to support some of the KPI requirements we need to make additional calculations using MDX expressions. In this case we can create a calculated member, which is similar to creating a computed value. In our project we effectively use calculation expressions to get specific measures needed for KPI. These calculations are allocated in the cube cell. Calculated measures are done in the Calculations tab of the Cube Design tab. For example Figure 19 shows the definition of a measure used to calculate online subscription rate of students.
After creating OLAP cubes, we can use Analysis Service measures to calculate all KPI in order to develop reports and to support decision makers in decision making activities. All the tasks in previous steps were made in order to be able to develop BI application and to deliver reports to QMS staff. We allocate all processes data information into a single repository called IPVC Data Warehouse and then we use OLAP Tool to analyze all the information in data cube. We define all necessary calculations to answer the KPI requirements. At this point, it is possible to browse the cube in the Browser tab of the Cube Designer, that allows to select dimensions and measures in order to visualize and analyze measures values by drilling into detail from summary, navigating hierarchies, sorting, ranking, filtering, charting and exporting. Figure 20 represents browser view to test developed report correctness.

Finally we are able to develop reports. For the purpose of this project, the reports were developed in two formats: Microsoft Excel and Web. In fact, the QMS managers perform their work using Microsoft Excel application, so it will be advantages for QMS persons to get the reports about IPVC processes in Microsoft Excel format with charts.
in their computers. We decide also to provide users with the access to the same reports using web browsers.

![Web browser tab of the Cube Designer](image)

Figure 20 - Web browser tab of the Cube Designer

According to the Agile BI methodology that were used in the implementation life cycle of our project, we use the reports as a documentation for validation processes. To interact with end users we present the Microsoft Excel reports and web reports in order to evaluate the correctness of reports and to be sure if it is exactly what they require.

Additionally, we implement digital dashboards using KPIs to support business requirements. BI dashboards are intended to provide decision makers with an overview of business performance at a glance, using attractive and intuitive visual interface. From a decision maker's perspective, dashboards provide a useful way to view data in a format that is easy to understand and to assimilate for managers.

In that context, we use the KPIs tab of the Cube Designer to define status levels, in order to be able to see KPI digital dashboard and identify IPVC education processes conditions at a single glance. Figure 21 represents the definition of KPI digital dashboards for the first IPVC process of KPI requirements.
To configure the KPI tab, we define the goal value to be attained in Goal Expression. Then the Status Expression is used to determine the current status of the KPI that will be used to picture status level. For example, in the case of students’ online subscription rate, the KPI value should reflect the following status level:

- Values greater than 70 percent should get a very good status;
- Values greater than 30 percent, but less or equal than 70.00, should get normal status;
- Values less or equal to 30 percent should get bad status.

To apply this status into KPI, we have to define the Status Expression field using the following Multidimensional Expression (MDX):

```
Case
   when [Measures].[AcademicServiceOnlineSubscriptionRate] > .70 then 1
   when [Measures].[AcademicServiceOnlineSubscriptionRate]>.30 and [Measures].[AcademicServiceOnlineSubscriptionRate]<= .70 then 0
   when [Measures].[AcademicServiceOnlineSubscriptionRate] <= .30 then -1
End
```

After defining the digital dashboard KPI, we can deploy this modification to the Analysis Service Database in order to be available to users. Figure 22 presents can see KPI deployment result shown in KPI Browser.
4.7 Answering IPVC Business Needs

The top position persons of IPVC schools need to analyze the data available from IPVC Quality Management systems (IPVC QMS). They would like to have analytical reports about all IPVC processes. As QMS staff uses Microsoft Excel to perform their work, they also would like to get BI reports in the same environment. The final purpose of this project is to implement a system which allows to calculate required KPIs and to deliver reports. In the following points, we present the business needs, DW models, OLAP cubes, reports and dashboards developed for the first four IPVC processes, namely, Academic Service, Environment Health and Safety, Alimentation and Accommodation. The remaining IPVC processes business needs and DW models are presented in Appendix B, since we were unable to validate these processes during the time of development as mentioned previously.

In general, the structure of data warehouse model contemplates a set of dimension attributes, as well as measures (for example: quantity, sum, and average, from others). However, in our project, some data warehouse models do not include measures, as we developed measures inside the cubes to calculate and answer KPI requirements through the use of functions and MDX expressions.

- Academic Service Business Needs

IPVC QMS staff needs to analyze all business processes which are related to academic service department work. They want to analyze the information across schools, courses, students, registration types and years and to be able to drill down to
the quarter, month and date level. Academic Service KPI requirement includes the percent of student’s online subscription (Table 2).

<table>
<thead>
<tr>

<td>Number of online subscriptions / Total number of subscriptions</td>
<td>%</td>
</tr>
</tbody>
</table>

Table 2 - Student online subscription KPI requirement

To answer this KPI requirement, we define the star model of academic service process illustrated in Figure 23, which is composed of a fact table and its connections to dimension tables. The model includes dimensions about students, schools, time, courses, locations and students registration type.

![Star model of student’s online subscription of academic service process](image)

Figure 23 – Star model of student’s online subscription of academic service process

To define the cube measures, we use count function from OLAP environment to get a measure (Fact Academic Service Count) that corresponds to the total number of students’ subscription. Using this measure we are able to calculate students’ online subscription rate applying the following MDX command:
Calculation name: AcademicServiceOnlineSubscriptionRate
MDX Expression: ([Measures].[Fact Academic Service Count],[Dim Registration Type],[Registration Name],&[Online])/[Measures].[Fact Academic Service Count]

Figure 24 presents the defined measures and dimensions for OLAP cube.

![OLAP cube of students online subscription of academic service process](image)

Figure 24 - OLAP cube of students online subscription of academic service process

After the definition of the cube, we produce a set of reports. Figure 25 presents an academic service report, which answers academic service process KPI requirements – “Students Online Subscription”. The report is in Microsoft Excel format and includes the following column fields: school name, course name, time and academic online service subscription rate. With this report QMS person can see the student’s online subscription rate in academic service by year, school and courses. Furthermore, QMS persons can also use drill down techniques and see the information in more detail if needed.

Figure 26 presents a graphical chart of students’ online subscription rate of academic service, where QMS person can visualize students’ online subscription rate by school and courses.

![Figure 26 - Chart report of students’ online subscription](image)

- **Environment, Health and Safety**

  In relation to Environment, Health and Safety (EHS) managers are interested in analyzing the information in IPVC schools related to simulacra, complaints and manuals. The first defined KPI requirement of EHS process is related with the number of simulacra in IPVC (Table 3).

<table>

Table 3 - Simulacra KPI requirement

Figure 27 presents the defined star model for EHS simulacra process, which is composed of one fact table and its connections to four dimension tables that include employee, schools, time and simulacra type (for example: water or fire).
The measure defined (Fact EHS Simulation Count) in this case is delivered using the count function that corresponds to the total number of simulacra.

Based on the defined cube, we create a simulacra report, which answers EHS process KPI requirements – “number of simulacra” (Figure 28). The Microsoft Excel report has column fields that include school name, year, simulation type and EHS simulacra number. With this Microsoft Excel report, QMS person can see the performed simulacra in IPVC by schools, simulation type and year. Furthermore, QMS persons can also use drill down techniques and see the information in more detail if needed.
Figure 29 presents a graphical chart of simulacra number by type and schools, from where QMS persons can easily analyze EHS process in IPVC and see EHS simulacra number by school and simulation type. QMS persons can also use drill down techniques and see the information in more detail. This chart can be useful to answer questions such as how many simulacra have been performed in each school by simulation type and year.

![Figure 29 - Chart report of EHS simulacra indicator](image)

Figure 30 presents a web format report of EHS simulacra process in IPVC. QMS persons can consult the EHS simulacra number by school, simulation type, year and quarter. Besides, web report allows end users to use drill down techniques and see the information in more detail if needed.

- **Social Service - Alimentation**

  IPVQ QMS staffs need to analyze data processes which are related to alimentation processes in IPVQ schools. They would like to analyze the information
about bars and canteens across the schools and time. For this purpose QMS managers have defined the KPI requirements. Table 6 presents the KPI requirement related to average cost of alimentation.

<table>

Table 6 - Alimentation average cost KPI requirement

In order to answer KPI average cost requirement, we define a star model for alimentation process (Figure 39), that includes two fact tables in order to store information about alimentation cost and served products.

![Figure 39 – Star model of average cost of alimentation process](image)

To calculate average cost, we develop a measure (Fact Alimentation Served Count) to get served products using the count function and a measure (Total Price Sum) to get the total price of products using the sum function on measure Total Price of alimentation cost fact table. Using these measures, we define the following calculated measure to answer KPI requirements:

Measure Name: Average_cost
MDX Expression: [Measures].[Total Price Sum]/[Measures].[Fact Alimentation Served Count]

Figure 40 illustrates a report in Microsoft Excel format that presents average costs by year, origin type, food type, school name and food price. With this report QMS person can see food price in IPVC by schools, food and time period.

</tbody>
</table>

Table 7 - Percentage of users in canteens KPI requirement

Figure 42 presents the star model created to get the percentage of users in canteens. The model includes fact tables with enrolled students in IPVC and served meals in canteens. The dimensions in the model are schools, time, food type, students and origin type.

Figure 42 – Star model of percentage of users in canteens of alimentation process.

To answer this KPI requirement, we develop two measures using the count function: one to determine the number of enrolled students (Fact IPVCstudents Count) and another to get the number of served meals (Fact Alimentation Served Count). Using these measures we are able to calculate the percentage of users that have meals at canteens through the definition of a calculated measure:
Measure name: UsersInCanteen
Expression: \[\frac{[\text{Measures}.[\text{Fact Alimentation Served Count}]}{[\text{Measures}.[\text{Fact IPVC students Count}]}}\]

Figure 43 presents a report with the percentage of users of alimentation services, which is in Microsoft Excel format and includes the following column fields: school name, time level and percentage of users in canteens.

<table>

</tr>
</tbody>
</table>

Table 8 - Average level of satisfaction KPI requirement

Figure 45 represents the star model of alimentation satisfaction level, which is composed of a fact table and its connections to dimension tables. The model includes the following dimensions: schools, time, satisfaction level, origin type and students.

![Star model of average satisfaction of alimentation process](image)

To answer this KPI requirement, we use the count and sum functions. With count function we develop measure (Fact Alimentation Satisfaction Count) to get number of responses and with sum function we develop measure (Satisfaction Value) to get sum of satisfaction values. In order to calculate average satisfaction level of canteen and bars and answer KPI requirement we apply following MDX command:

Measure name: AVG_SatisfactionLevel

MDX Expression: `[Measures].[Satisfaction Value]/[Measures].[Fact Alimentation Satisfaction Count]`
Figure 46 presents alimentation satisfaction level in that includes following column fields: school name, year, origin type and average satisfaction level. Figure 47 represents charts report of alimentation satisfaction levels in schools.

![Microsoft Excel report of alimentation average satisfaction level](image)

![Chart report of alimentation average satisfaction level](image)
- **Social Service - Accommodation process**

  IPVC QMS staff has defined KPI to analyze services, which are related to accommodation process. The KPI list includes the occupancy rate of residences, the variation of housed students in residences and users’ satisfaction.

  The first KPI requirement is about occupancy rate of residences (Table 9).

<table>
<thead>
<tr>
<th>Process</th>
<th>Process/ Sub-process</th>
<th>Indicator</th>
<th>Calculation Formula</th>
<th>Unit of Measure</th>
</tr>
</thead>
<tbody>
<tr>
<td>Social Service</td>
<td>Accommodation</td>
<td>Occupancy rate of residences</td>
<td>Number of housed students / total number of beds</td>
<td>%</td>
</tr>
</tbody>
</table>

Table 9 - Occupancy rate of residences KPI requirement

To answer occupancy rate KPI requirement, we define the star model of accommodation occupancy process, which is illustrated in Figure 48.

![Star model of occupancy rate of accommodation process](image)

Figure 48 – Star model of occupancy rate of accommodation process

In order to calculate occupancy rate and answer KPI requirements we have to define the following measures:
• The total number of beds in residences (Number Of Available Beds) using the sum function on fact table measure NumberOfAvailableBeds;
• The number of housed students (Fact Accommodation Occupancy Count) using the count function;
• The occupancy rate (AccommodationOccupancyRate) using the following MDX expression: 
  \[ \frac{\text{[Measures].[Fact Accommodation Occupancy Count]}}{\text{[Measures].[Number Of Available Beds]}} \]

Figure 49 presents a report in Microsoft Excel format that permits to visualize accommodation occupancy by residence name and year. Furthermore, QMS persons can also use drill down techniques and see the information in more detail. Figure 50 presents a bar chart report of accommodation occupancy rate in IPVC.

<table>
<thead>

![Figure 50 - Chart report of accommodation occupancy rate](chart2.png)
Table 10 presents the second KPI requirement of IPVC accommodation process related to the variation of housed students.

<table>
<thead>
<tr>
<th>Process</th>
<th>Process/Sub-process</th>
<th>Indicator</th>
<th>Unit of Measure</th>
<th>Calculation Formula</th>
</tr>
</thead>
<tbody>
<tr>
<td>Social Service</td>
<td>Accommodation</td>
<td>Homologous variation of housed students</td>
<td>%</td>
<td>Number of housed students in year n / Number of housed students in year n-1</td>
</tr>
</tbody>
</table>

Table 10 - Housed students’ variation KPI requirements

To answer homologous variation of housed students KPI requirement, we use the fact table of accommodation occupancy table presented in Figure 48. In this case, we have to use parallel period function, which can be used to return a member from a prior period in the same relative position as a specified member [1 p. 310]. Using this function, we define a calculated measure using a MDX expression as follows:

Measure name: AccommodationVariation

MDX Expression: ([Measures].[Fact Accommodation Occupancy Count]/
((ParallelPeriod([Dim Time].[Year-Quarter-Month-TimeDate].[Year],1,
[Dim Time].[Year-Quarter-Month-TimeDate].currentmember),
[Measures].[Fact Accommodation Occupancy Count])) - 1)

Figure 51 presents the accommodation variation rate which answers KPI requirements. The report is presented in Microsoft Excel format and allows to analyse variation rate by residence name and year. The variation rate of housed students can also be presented using a chart as illustrated in Figure 52.
Table 11 presents the third KPI requirement for IPVC accommodation process which is related to users’ satisfaction.

<table>
<thead>
<tr>

4.8 Key Performance Indicators (KPI) in Dashboard Report

As we can observe the developed solution gives the ability to create reports that allows the QMS managers to analyze services performance through the visualization of KPIs in different ways. This type of report gives a set of dynamic tools to analyse data, like drilling into detail from summary, navigating hierarchies, sorting, ranking, filtering, charting and exporting. This tool offers a great independence in the way that users interact with the information facilitating the support decision making activities.

On the order hand, BI solutions usually include the capacity to create dashboards for decision makers. BI dashboards are intended to provide decision makers with an overview of business status at a single glance, using appealing and intuitive graphical interface that can be used with a few simple clicks of the mouse. From a decision maker's point of view, dashboards provide a effective and simple approach to view data and information using components such as single metrics, graphical trend analysis, capacity gauges, geographical maps and variance comparisons, which are presented in a format that is easy to understand and use by managers [37].

As previously mentioned, SQL Server 2005 offers the possibility to create KPI digital dashboards. In this project, we create an example of a dashboard for some of the KPI requirements. In this sense, we define the limits for each status level that is used to picture status level and deploy KPI dashboard. Figure 56 presents the digital dashboard created with KPI value, goal and status for academic service online subscriptions, alimentation cost, alimentation experience, alimentation satisfaction level, EHS number of manuals, EHS number of complaints, EHS number of simulacra, accommodation variation, accommodation occupancy rate and accommodation satisfaction level.

In the context of this project, we have decided to experiment a different solution in order to create dashboards with the objective to provide decision makers with different types of functionalities in terms of KPI visualization. As mentioned previously, we select the Tableau software which gives a set of functionalities to provide interactive data visualizations, as well as dashboards and reports. Through the use of this software, it is possible to connect SQL Server Analysis Service cube and create the structure of dashboards to present KPI using reports and charts. Figure 57 illustrates an example developed in this project that presents KPI values using different type of presentation.
Figure 56 - IPVC digital dashboard report

Figure 57 - Dashboard report with Tableau Software
Chapter 5 - Conclusions and Future Work

5.1 Conclusion

The main objective of this project was to develop a Decision Support System (DSS) for Quality Management System (QMS) departments in a High Educational Institution, in particular in the Polytechnic Institute of Viana do Castelo. In the context of our project, we studied and explored Business Intelligence (BI) systems and the benefits that can bring to educational institutions. In general, BI is a group of software programs and technologies that gives opportunity to gather an increasing data from business operations, store them in a single data repository for analyzing and delivering real time reports in order to support the decision making activities in the organization. One of the sources that BI can use to get business information could be from QMS. QMS allows the definition of a set of processual and organizational documentation in order to guide and achieve high levels of efficiency, improve the business processes performance and the internal and external quality of the services provided. On the other hand, QMS can be a valuable source of information to deliver Key Performance Indicators (KPI) for decision makers to support the task to control and manage the services performance. In the case of IPVC, a set of KPIs have been defined by stakeholders to control, evaluate, monitor and improve business processes. For this reason, we consider that BI solution can be a valuable and necessary solution to support business needs that will enable to provide KPI reports and gives opportunity to measure effectiveness of business performances in all departments.

In the context of project “Key Performance Indicators in a High Educational Institutions: A Business Intelligence Approach”, we focused on the development of a BI systems solution in order to support the analyses of the IPVC processes performance. In this context we implemented Key Performance Indicators reports for the QMS staff in order to make available needed information, as well as to assist decision maker persons to perform their work and to increase the analysis and decision making activities.

To achieve these goals, we select BI system SQL Server 2005 tool in order realize our expected results. We apply agile BI methodology and divide BI implementation lifecycle process into five steps: Story of Conference, Task Plans,
Development, Sprint Demo and Retrospective [34]. Following the Agile methodology framework we have performed the following main tasks: gather, collect and analyze KPI requirements, define star models, define dimensions and measures, develop Educational Data Warehouse (EDW) and OLAP interface, develop reports, and finally, present demo version of BI project to end users with the purpose of validation.

During the implementation of the project a top down approach was used. Our starting point was the IPVC schools Key Performance Indicators (KPI) requirements and forms. With these requirements we define and built an Educational Data Warehouse (EDW) to prepare an environment to allocate all schools operational data into one source. The developed IPVC EDW enables QMS person to access needed information in real time and get reports. It will give advantage to IPVC in better management and improvement of educational quality and processes. With BI Online Analytical Processes tool (OLAP) we analyze all the data and make calculations to get measures in order to support the KPI requirements. Then we were able to provide end-users with reports in Microsoft Excel programs and web browsers.

One of the main advantages that this project brings to IPVC is data warehousing, where all processes are materialized into one data source from where IPVC can access all kind of data depending on the business requirements. Using the DW, QMS persons can access KPI state at a single glance at all level of IPVC which will help to evaluate, control and monitor all processes. As a result, data warehousing gives huge benefits to IPVC, by the fact that it allows to achieve a level of maturity that gives the opportunity to be ready to answer to new requirements and implement multiple BI projects in the organization. In this context, the existence of DW will help organizations to concentrate, focus and deliver more time to develop BI reports, which gives opportunity to be in forward against competitors. In the case of IPVC BI project, developed DW allows to apply next generation BI tool in order to deliver advanced reports in a very short time for IPVC staff. For this purpose we use Tableau Software to deliver dynamic reports which gives opportunity to explore reports and manipulate the data more efficiently and effectively.

This project was the first attempt to apply Business Intelligence system in IPVC QMS schools. The developed project brings a list of valuable benefits to IPVC, namely:
• Allocate all Institute processes data into a single repository Data Warehouse. It gives the ability to access the information related to the Institute and deliver the reports for decision makers;
• IPVC Data Warehouse has historical perspective and gives the opportunities develop customized reports.
• Monitor and evaluate predefined Key Performance Indicators (KPI) and assess the state of education performances in a very short time.
• Decision makers are provided with reports about KPI in timely manner. They will not lose time searching information to perform their work and they will more concentrate to improve the quality and services.
• Decision makers of IPVC can use BI tool successfully to evaluate and monitor all activities and processes at a single glance and, like that, prescribe timely actions for the improvement.
• Ability to deliver new IT solutions quickly. It allows IPVC to be mature and be ready to quickly develop different kind of BI projects in the future.

Finally, we would like to mention that, during the implementation process, we faced some problems that hampered the project execution, that are mainly related with the fact that this project was not required by top managers of IPVC. For that reason, we encountered several difficulties, namely, to get and understand IPVC KPI requirements that was sometimes imprecise and ambiguous, to access data sources of QMS system, and to access and schedule meetings with the right persons in order clarify KPI requirements and validate processes. For that reason, we have developed DW models and generated reports for all processes but we were able to validate only four processes. However we handle to overcome these problems and we develop a first implementation of a BI DSS for IPVC, considering that the results of this project are a valid contribution for the provision of tools to support decision makers of IPVC.

The result of our project shows the advantages and benefits that integration of BI applications and QMS can bring to IPVC, contributing to the provision of tools to support management and decision making activities. The developed decision support system could simplify the IPVC work and it will help decision persons to make timely decisions based on real time information in order to improve educational processes.
5.2 Future work

In the frame of this thesis work we focused in developing a BI system in order to support the KPI requirements for the IPVC schools. However there are some issues that could be the subject for future work, namely:

- Complete the validation of all processes;
- Improve business layers, to improve the reports and increase decision makers’ satisfaction.
- Expend and improve the decision support system by applying data mining techniques to discover interesting patterns inside the institute in order to predict future trends and to plan institution work in a better way.

Appendix B – IPVC business needs and DW models

B.1. Introduction

In the frame of this project we had access to the Key Performance Indicators (KPI) list to develop the BI application. In general, IT projects development life cycle requires intensive interaction with business managers to define and specify the requirements in order to understand the business needs. As it is frequent in this kind of projects, the provided requirements were ambiguous, so we need to get explanations from QMS personnel. For this purpose, during the project implementation process, we would have to schedule a set of meetings in order to understand KPI requirements. However, QMS managers were unavailable to schedule those meetings to clarify the requirements or the scheduled meetings were not enough to understand some processes. For that reason, we decide to interpret the business needs using other sources, such as internet, interviews with front office personnel and teachers from other universities. As QMS managers do not had time to validate all processes, we present the processes that we have developed, being only presented the models.

B.2. Implementation process

In this appendix we present a set of multi-dimensional data-models created in this project. The option to present models in appendix is due to the fact that QMS managers do not had time to validate processes and were not involved intensely in agile methodology steps during the BI project implementation. Since we were not able to validate all processes, for the reason already stated in this document, we choose an approach that includes the study of the KPI requirements of some processes. Based on the document provided by QMS staff, we studied KPI requirements and try to understand information requirements in order to develop multi-dimensional model to support these requirements. However, there is several information, in particular the defined measures, for which we were unable to understand purposes as they were defined in KPI requirements list. Nevertheless, we manage to define some data models to support the information requirements. In the future perspective, when it will be possible to perform the validation of processes for KPI, the developed models will be a
good starting point to do the calculation and easily change formulas to get new kind of measures or to improve the defined measures.

In this context, we present in the next section we present the business needs, KPI requirement, star models and measures developed in this project in order to answer the KPI requirements list. For each KPI, we will present the definition as it was listed on the KPI requirement document. We ignored measures that we did not have a minimum understanding of its meaning. Finally, we would like to underline one more time that in this appendix we present the KPI with any kind of validation.

B.3. IPVC Business Needs

- Social Service - Scholarship

IPVC QMS staff has needs to analyze all processes which are related to scholarships in IPVC schools. They are interested in analyzing the information about interviews and visits to students applying for scholarships, as well as users’ satisfaction related to provided services.

Table 1 presents IPVC Scholarship process KPI requirements list provided by QMS managers.

<table>
<thead>
<tr>
<th>Process</th>
<th>Process/Sub-process</th>
<th>Indicator</th>
<th>Calculation Formula</th>
<th>Unit of Measure</th>
</tr>
</thead>
<tbody>
<tr>
<td>Social Service</td>
<td>Scholarships</td>
<td>Percentage of interview conducted for students applying for scholarship of 1st year and 1st enrollment</td>
<td>Number of interviews / Number of students applying for scholarship of 1st year and 1st enrollment</td>
<td>%</td>
</tr>
<tr>
<td>Social Service</td>
<td>Scholarships</td>
<td>Percentage of domiciliary visits to students applying for scholarship of 1st year and 1st enrollment</td>
<td>Number of home visits / Number of students applying for scholarship of 1st year and 1st enrollment</td>
<td>%</td>
</tr>
</tbody>
</table>

Table 1 - Scholarship interviews and domiciliary visits KPI requirements.

To answer the first two KPI requirements shown above, we define a star model for scholarship process as illustrated in Figure 1, which is composed of fact table and
dimension tables which includes schools, time, students, courses, course year and enrollment number. The fields withInterview and withHomeVisit of fact table will have a value of zero or one indicating, respectively, if it has been conducted an interview or made a domiciliary visit to the student or not.

Figure 58 – Star model of scholarship interviews and domiciliary visits.

To answer KPI requirements we define the following measure:

- Percentage of interview conducted for students applying for scholarship of 1st year and 1st enrollment:
  
  Measure name: IntervStudents

  Expression: ([Measures].[With Interview],[Dim Course Year],[Course Year].[1st],[Dim Enrollment Number],[Enrollment Number].[1st])/([Measures].[Fact Scholarship Apply Count],[Dim Course Year],[Course Year].[1st],[Dim Enrollment Number],[Enrollment Number].[1st])

- Percentage of domiciliary visits to students applying for scholarship of 1st year and 1st enrollment:
  
  Measure name: DomVisitsStudents
Expression: ([Measures].[With Home Visit],[Dim Course Year 1],[Course Year].&[1st],[Dim Enrollment Number],[Enrollment Number].&[1st])/([Measures].[Fact Scholarship Apply Count],[Dim Course Year 1],[Course Year].&[1st],[Dim Enrollment Number],[Enrollment Number].&[1st])
Appendix A – IPVC business needs and DW models

B.1. Introduction

In the frame of this project we had access to the Key Performance Indicators (KPI) list to develop the BI application. In general, IT projects development life cycle requires intensive interaction with business managers to define and specify the requirements in order to understand the business needs. As it is frequent in this kind of projects, the provided requirements were ambiguous, so we need to get explanations from QMS personnel. For this purpose, during the project implementation process, it was necessary to schedule a set of meetings in order to understand KPI requirements. However, QMS managers were unavailable to schedule those meetings to clarify the requirements or the scheduled meetings were not enough to understand some processes. For that reason, we decided to interpret the business needs using other sources, such as internet, interviews with front office personnel and teachers from other universities. As QMS managers do not had time to validate all processes, we present the processes that we have developed, being only presented the models.

B.2. Implementation process

In this appendix we present a set of multi-dimensional data-models created in this project. The option to present models in appendix is due to the fact that QMS managers do not had time to validate processes and were not involved intensely in agile methodology steps during the BI project implementation. Since we were not able to validate all processes, for the reason already stated in this document, we choose an approach that includes the study of the KPI requirements of some processes. Based on the document provided by QMS staff, we studied KPI requirements and try to understand information requirements in order to develop multi-dimensional model to support these requirements. However, there was several information, in particular the defined measures, for which we were unable to understand purposes as they were defined in KPI requirements list. Nevertheless, we managed to define some data models to support the information requirements. In the future, when it will be possible to perform the validation of
processes for KPI, the developed models will be a good starting point to do the calculation and easily change formulas to get new kind of measures or to improve the defined measures.

In this context, we present in the next section the business needs, KPI requirement, star models and measures developed in this project in order to answer the KPI requirements list. For each KPI, we will present the definition as it was listed on the KPI requirement document. We ignored measures that we did not have a minimum understanding of its meaning. Finally, we would like to underline one more time that in this appendix we present the models defined for KPI with any kind of validation.

B.3. IPVC business needs

- Social Service - Scholarship

IPVC QMS staff has needs to analyze all processes which are related to scholarships in IPVC schools. They are interested in analyzing the information about interviews and visits to students applying for scholarships, as well as users’ satisfaction related to provided services.

Table 1 presents IPVC Scholarship process KPI requirements list provided by QMS managers.

<table>
<thead>
<tr>
<th>Process</th>
<th>Process/Sub-process</th>
<th>Indicator</th>
<th>Calculation Formula</th>
<th>Unit of Measure</th>
</tr>
</thead>
<tbody>
<tr>
<td>Social</td>
<td>Scholarships</td>
<td>Percentage of interview conducted for students applying for scholarship of 1st year and 1st enrollment</td>
<td>Number of interviews / Number of students applying for scholarship of 1st year and 1st enrollment</td>
<td>%</td>
</tr>
<tr>
<td>Service</td>
<td>Scholarships</td>
<td>Percentage of domiciliary visits to students applying for scholarship of 1st year and 1st enrollment</td>
<td>Number of home visits / Number of students applying for scholarship of 1st year and 1st enrollment</td>
<td>%</td>
</tr>
</tbody>
</table>

Table 1 - Scholarship interviews and domiciliary visits KPI requirements.

To answer the first two KPI requirements shown above, we define a star model for scholarship process as illustrated in Figure 1, which is composed of a fact table and dimension
tables which include schools, time, students, courses, course year and enrollment number. The fields withInterview and withHomeVisit of fact table will have a value of zero or one indicating, respectively, if it has been conducted an interview or made a domiciliary visit to the student or not.

![Star model of scholarship interviews and domiciliary visits.](image)

Figure 1 – Star model of scholarship interviews and domiciliary visits.

To answer KPI requirements we define the following measure:

- Percentage of interview conducted for students applying for scholarship of 1st year and 1st enrollment:

  Measure name: IntervStudents
  Expression: \( \frac{([\text{Measures}].[[\text{With Interview}],[\text{Dim Course Year}],[\text{Course Year}]&[1st], [\text{Dim Enrollment Number}],[\text{Enrollment Number}]&[1st]) / ([\text{Measures}].[[\text{Fact Scholarship Apply Count}],[\text{Dim Course Year}],[\text{Course Year}]&[1st], [\text{Dim Enrollment Number}],[\text{Enrollment Number}]&[1st])} {1} \)

- Percentage of domiciliary visits to students applying for scholarship of 1st year and 1st enrollment:

  Measure name: DomVisitsStudents
Expression: ([Measures].[With Home Visit],[Dim Course Year 1],[Course Year].&[1st],[Dim Enrollment Number],[Enrollment Number].&[1st])/([Measures].[Fact Scholarship Apply Count],[Dim Course Year 1],[Course Year].&[1st],[Dim Enrollment Number],[Enrollment Number].&[1st])

Another KPI requirement of scholarships process is related to users’ satisfaction (Table 2)

<table>
<thead>
<tr>
<th>Process</th>
<th>Process/Sub-process</th>
<th>Indicator</th>
<th>Calculation Formula</th>
<th>Unit of Measure</th>
</tr>
</thead>
<tbody>
<tr>
<td>Social Service</td>
<td>Scholarships</td>
<td>Average level of satisfaction of scholarship services</td>
<td>( \frac{\sum (\text{question rating \times weighting})}{\text{number of response}} )</td>
<td>Inquiry scale</td>
</tr>
</tbody>
</table>

Table 2 - Scholarships satisfaction KPI requirement.

To answer the last KPI requirements of scholarship process, we define the star model illustrated in Figure 2, which is composed of a fact table to register satisfaction levels and dimension tables, which includes schools, time, students, course, and scholarship satisfaction type.

![Star model scholarship satisfaction process](image)

For this KPI, we define a calculated measure to determine the average level of satisfaction of scholarship services using the following formula:

Calculated measure name: AVGsatisfactionArea

MDX expression: [Measures].[Question Weighted]/[Measures].[Weighting]
International Cooperation

IPVC QMS staff has needs to analyze international cooperation department’s work in IPVC schools. They need to be able to analyze the information about partnerships, agreements, protocols and student, teacher and non-teacher mobility.

Table 3 represents IPVC International cooperation mobility KPI requirement.

<table>
<thead>
<tr>
<th>Process</th>
<th>Process/Sub-process</th>
<th>Indicator</th>
<th>Calculation Formula</th>
<th>Unit of Measure</th>
</tr>
</thead>
<tbody>
<tr>
<td>International Cooperation</td>
<td>International</td>

<td>%</td>
</tr>
<tr>
<td></td>
<td>Cooperation</td>
<td></td>
<td>Variation of number of non-teachers received per year</td>
<td>%</td>
</tr>
</tbody>
</table>

Table 3 - International cooperation mobility KPI requirements

Figure 3 presents the fact table created to store information about mobility of teachers, students and non-teachers and dimension tables about schools, time, courses, mobility type (sent or received) and group type (teacher, student or non-teacher).

Figure 3 – Star model of international mobility.
To answer KPI requirements we define the following measure:

- **Variation of number of teachers sent per year:**

  Measure name: `NumberTeachersSent`
  Expression: `([Measures].[FactIntMobility Count],[Dim Group Type],[GroupName].&[Teacher], [Dim Mobility Type].[Mobility Name].&[Sent])`

  Measure name: `VarNumberTeachersSent`
  Expression: `([Measures].[NumberTeachersSent]/(ParallelPeriod([Dim Time].[Year],[Year], 1, [Dim Time].[Year].currentmember), [Measures].[NumberTeachersSent]))-1`

- **Variation of number of teachers received per year:**

  Measure name: `NumberTeachersReceived`
  Expression: `([Measures].[FactIntMobility Count],[Dim Group Type],[GroupName].&[Teacher], [Dim Mobility Type].[Mobility Name].&[Received])`

  Measure name: `VarNumberTeachersReceived`
  Expression: `([Measures].[NumberTeachersReceived]/(ParallelPeriod([Dim Time].[Year],[Year], 1, [Dim Time].[Year].currentmember), [Measures].[NumberTeachersReceived]))-1`

- **Variation of number of students sent per year:**

  Measure name: `NumberStudentsSent`
  Expression: `([Measures].[FactIntMobility Count],[Dim Group Type],[GroupName].&[Student], [Dim Mobility Type].[Mobility Name].&[Sent])`

  Measure name: `VarNumberStudentsSent`
  Expression: `([Measures].[NumberStudentsSent]/(ParallelPeriod([Dim Time].[Year],[Year], 1, [Dim Time].[Year].currentmember), [Measures].[NumberStudentsSent]))-1`

- **Variation of number of students received per year:**

  Measure name: `NumberStudentsReceived`
  Expression: `([Measures].[FactIntMobility Count],[Dim Group Type],[GroupName].&[Student], [Dim Mobility Type].[Mobility Name].&[Received])`

  Measure name: `VarNumberStudentsReceived`
Expression: ([Measures].[NumberStudentsReceived]/(ParallelPeriod([Dim Time].[Year].[Year], 1, [Dim Time].[Year].currentmember), [Measures].[NumberStudentsReceived]))-1

- Variation of number of non-teachers sent per year:
  Measure name: NumberNTeachersSent
  Expression: ([Measures].[FactIntMobility Count],[Dim Group Type].[GroupName].&[Non-teacher], [Dim Mobility Type].[Mobility Name].&[Sent])
  Measure name: VarNumberNTeachersSent
  Expression: ([Measures].[NumberNTeachersSent]/(ParallelPeriod([Dim Time].[Year].[Year], 1, [Dim Time].[Year].currentmember), [Measures].[NumberNTeachersSent]))-1

- Variation of number of non-teachers received per year:
  Measure name: NumberNTeachersReceived
  Expression: ([Measures].[FactIntMobility Count],[Dim Group Type].[GroupName].&[Non-teacher], [Dim Mobility Type].[Mobility Name].&[Received])
  Measure name: VarNumberNTeachersReceived
  Expression: ([Measures].[NumberNTeachersReceived]/(ParallelPeriod([Dim Time].[Year].[Year], 1, [Dim Time].[Year].currentmember), [Measures].[NumberNTeachersReceived]))-1

Table 4 presents IPVC International cooperation partnerships KPI requirement.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Table 4 - International Cooperation partners KPI requirement

Figure 4 represents fact table of international cooperation protocols and its connections to dimension tables. We have the following dimensions: schools, time, agreement type, partners and protocol types.
To answer KPI, we define the following measure:

**MDX command**

Calculated measure name: ProtocolRate (Partners)

MDX code: [Measures].[Fact Int Coop Protocols Count]/365

Calculated measure name: AgreementRate (Partners)

MDX code: ([Measures].[Fact Int Coop Protocols Count],[Dim Agreement Type].[All])/365

- **Creation and Restructuring of Courses**

  IPVC QMS staff would like to analyze courses creation and restructuring process in schools. They need to begin analyze the information in schools about proposed and restructured of courses in each semester.

  Table 5 represents creation restructuring of courses KPI requirement.

<table>
<thead>
<tr>
